

### AI-POWERED HEALTHCARE COMPANION: REVOLUTIONIZING HOSPITAL MANAGEMENT THROUGH INTELLIGENT CHATBOT

<sup>1</sup>Annapoorani V, <sup>2</sup>Priyadharshini K, <sup>3</sup>Ramya E, <sup>4</sup>Sathiyapriya R, <sup>5</sup>Shalini M, <sup>6</sup>Soundappan V <sup>1,6</sup>Assistant Professor, <sup>2,3,4,5</sup>Student, Department of Electronics and Communication Engineering, Mahendra Institute of Technology, Namakkal (Dt), Tamilnadu, India.

#### ABSTRACT

People frequently neglect to take proper care of their health in today's fast-paced world. People attempt to avoid seeing a doctor for a diagnosis because they find it unpleasant or they are pressed for time. Having access to healthcare is essential to living a healthy life. However, getting a doctor's consultation when you have health concerns is very difficult. The suggested concept is to use artificial intelligence to develop a medical chatbot that, before speaking with a doctor, can identify a disease and provide basic information about it. The purpose of the medical chatbot is to lower healthcare costs and increase accessibility to medical information. Some chatbots function as medical reference books, educating patients about their conditions and promoting better health. The true value of a chatbot to the user can only be realized when it is able to diagnose any type of illness and provide relevant information. Chatbots are computer programs that use machine learning algorithms to simulate human conversation. It is intended to be the best virtual assistant available, assisting with everything from completing tasks to answering inquiries about health care. Right now, one of the greatest emerging technologies is chatbots. It is undoubtedly among the most sophisticated and efficient technologies available. However, in order to complete many tasks, chatbots must also become more effective in the medical field. In order to solve this issue, the project offers a platform for people to communicate with highly trained chatbots that use machine learning algorithms on datasets. Instead of using a logical approach to computation, machine learning algorithms use a more organic approach. The dataset they are trained on determines the output. Real-time medical systems can be implemented, and the text results can be converted to audio format.

# KEYWORDS: Machine Learning, Natural Language Processing, Chatbots, Artificial Intelligence, Medical system

#### **INTRODUCTION**

A computer software meant to mimic human-user communication, particularly over the Internet. More officially, chatbots are called conversational agents in the scientific literature. The phrases "chatbot" and "conversational agent" will be used interchangeably in this article. The fundamental idea behind all chatbots is to communicate (mostly) through text messages with human users, acting as if it could comprehend what is being said and respond to the user accordingly.

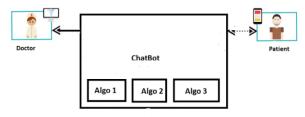

Fig.1 Chat bot

Conversations between computers and humans have existed for as long as computer science itself. In fact, Alan back in 1950. Turing developed а straightforward test known as the Turing test, in which a human judge would have to determine whether or not the thing they are text-chatting with is a computer program. This is beneficial for conversational agent design since it frees them from having to possess (possibly) limitless domain knowledge. As a result, they can concentrate on a narrow range of extremely particular topics, like assisting customers with restaurant reservations. Additionally, users usually start a chatbot encounter with a goal in mind for the conversation, which is another basic assumption that chatbot designers keep in mind. This therefore affects the sequence of topics and the flow of the conversation.

#### HISTORY

In 1966, ELIZA, a computer program that mimicked a psychiatrist and rephrased user input using simple (by today's standards) Natural Language Processing techniques, became the first example of a conversational agent. The program deceived a huge number of people by appearing to comprehend the user's concerns, even though it was quite simple. Joseph Weizenbaum, the man who created it, even stated that his secretary would beg him to step aside so she could speak with ELIZA in private.

Then, over a few decades, chatbots mostly adopted ELIZA's methodology with a few small innovations, such as speech synthesis and emotion management. Then, in 2001, Active Buddy, Inc. (now Colloquis) released Smarter Child, a conversational agent that worked with MSN Messenger and AOL Instant Messenger. Smarter Child was developed to give immediate access to news, sports scores, weather reports and other information, drawing inspiration from the popularity of instant messaging services like SMS. The primary innovation was that Smarter Child stored valuable information for its users and was linked to a knowledge source. Unfortunately, bots on those sites were eventually rendered obsolete by the technological constraints of Natural Language Processing at the time.

A group at IBM developed the next breakthrough for conversational bots through the Watson AI project, which has been under development since 2006. From an NLP perspective, Jeopardy is intriguing since the questions use a lot of word play and need quick information retrieval from large knowledge bases. Regretfully, this AI's previous incarnation was limited to providing one-liner responses and was unable to hold a meaningful dialogue with another person. Virtual assistants, like those from Apple (Siri), Microsoft (Cortana), Google (Google assistant), Amazon (Alexa)and others, began to proliferate in the early 2010s. Both goal-oriented dialog and the concept of conversation were introduced to the field by those agents.

#### **CHATBOTS IN VARIOUS INDUSTRIES**

These computer programs, known as chatbots, converse with users in natural language. The process is the same for all chatbots, even though they are each unique in their own domain. The use of chatbots has spread from customer service to matters of life and death. Chatbots are entering the healthcare industry and can help solve many of its problems. Health and fitness chatbots have begun to attract a market. Last year Facebook has started allowing companies to create Messenger chatbots to communicate with users. A great example is HealthTap – the first company to release a health bot on the Messenger app. It allows users to ask medical questions and receive answers from doctors. Fitness bots dominate this category, but there are plenty of medical bots worth attention too.

Chatbots are far from widespread adoption in healthcare, but they are on the rise. Chatbots are also appearing in the healthcare industry. A study suggested that physicians in the United States believed that chatbots would be most beneficial for scheduling doctor appointments, locating health clinics or providing medication information. ChatGPT is able to answer user queries related to health promotion and disease prevention such as screening and vaccination. WhatsApp has teamed up with the World Health Organization (WHO) to make a chatbot service that answers users' questions on COVID-19.

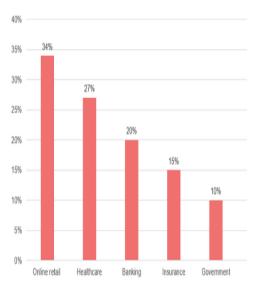

Fig.2 Graph of chatbot adaption

In 2020, The Indian Government launched a chatbot called MyGov Corona Helpdesk, that worked through WhatsApp and helped people access information about the Coronavirus (COVID-19) pandemic.

Certain patient groups are still reluctant to use chatbots. A mixed-methods study showed that people are still hesitant to use chatbots for their healthcare due to poor understanding of the technological complexity, the lack of empathy and concerns about cyber-security. The analysis showed that while 6% had heard of a health chatbot and 3% had experience of using it, 67% perceived themselves as likely to use one within 12 months. The majority of participants would use a health chatbot for seeking general health information (78%), booking a medical appointment (78%) and looking for local health services (80%). However, a health chatbot was perceived as less suitable for seeking results of medical tests and seeking specialist advice such as sexual health.

The analysis of attitudinal variables showed that most participants reported their preference for discussing their health with doctors (73%) and having access to reliable and accurate health information (93%). While 80% were curious about new technologies that could improve their health, reported only seeking a doctor when 66% experiencing a health problem and 65% thought that a chatbot was a good idea. 30% reported dislike about talking to computers, 41% felt it would be strange to discuss health matters with a chatbot and about half were unsure if they could trust the advice given by a chatbot. Medical chatbots can be configured to deliver regular updates on recent research papers, journal articles and clinical trial outcomes relevant to a medical professional's specialty. The chatbots can also analyze and summarize key findings from new studies, providing a concise overview of the latest research. Medical professionals can engage in interactive learning sessions with the chatbot. They can ask specific questions about new treatments, drugs or procedures and the chatbot can provide detailed explanations, pulling information from recent studies or medical databases. For more advanced applications, chatbots can assist in clinical decision-making by providing information from the latest research that may impact treatment options and patient care strategies. Chatbots can summarize complex research papers, making them more accessible and easier to understand. This feature is particularly useful for

quickly grasping the key points of extensive or highly technical studies. Keeping track of the latest pharmaceutical developments, including new medications and their interactions, is crucial. Chatbots can provide timely updates in this area. Chatbots can also update medical professionals about changes in guidelines, standards and regulatory requirements, ensuring that practices remain compliant and aligned with current best practices.

#### **MEDICAL CHATBOTS**

Medical chatbots can automate many of the routine tasks that healthcare providers currently do, such as answering frequently asked questions, scheduling appointments and refilling prescriptions. This frees up healthcare providers to spend more time with their patients and focus on more complex medical care. Medical chatbots can help reduce healthcare costs by reducing the need for unnecessary doctor visits and by improving patient outcomes. For example, chatbots can help patients to better understand their conditions and to make better choices about their health care.

A human input is compared to the chatbot's knowledge base. Since chatbots primarily use artificial intelligence, we have chosen to use this ability to contribute to the field of health informatics. The low level of patient engagement that occurs after patients leave clinics or hospitals is frequently blamed for the high cost of our healthcare system. Numerous studies conducted in this field have demonstrated that chatbots can deliver healthcare at a reasonable cost and with better results.

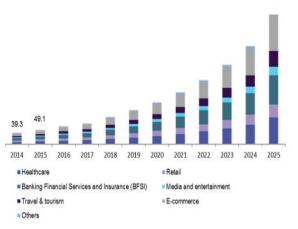

Fig.3 The future of chatbots

By providing prompt answers to the questions posed by the user, the scheme aims to bridge the communication gap between patients and healthcare providers. The majority of people in today's world are probably internet addicts, but they do not give their personal health much thought. They avoid visiting the hospital for minor issues that could develop into major illnesses down the road. Creating forums with questions and answers is quickly replacing the tedious process of searching through a list of web documents that might be pertinent. Many of the current systems have drawbacks, such as the fact that patients must wait a long period for expert acknowledgement and do not receive a prompt response. Certain procedures might charge a fee for conducting live chat or phone calls with doctors via the internet. Through the use of Natural Language Processing, this system enables computer-tocomputer communication (NLP). Three analyses are available that comprehend natural language. i.e., the primary linguistic relations are identified in order to parse the sentences' subject and object. A chatbot is an entity that uses methods like Natural Language Processing (NLP) to mimic human conversation in its specific, approved setup while speaking or writing in text. Creating a user interface for sending and receiving input is one way to develop a chatbot application. It is a system that communicates with the user by monitoring the interaction's status and remembering previous commands to provide functionality.

#### PROBLEM STATEMENTS

The problem statement outlines several critical healthcare challenges that a medical chatbot can help address:

#### • Health information overload

The chatbot can serve as a reliable source of medical information, providing users with accurate, evidence-based answers to their health-related questions. By synthesizing complex medical concepts into understandable language and directing users to credible sources, the chatbot helps mitigate information overload and promotes informed decision-making. With the abundance of medical information available online, patients often struggle to find accurate, relevant and trustworthy information. This information overload can lead to confusion, anxiety and inappropriate self-diagnosis or treatment.

#### • Patient Education and Empowerment:

Through interactive conversations, the chatbot can educate users about their health conditions, treatment options and preventive measures.

It can offer personalized recommendations based on users' health profiles and preferences, empowering them to take an active role in managing their health and well-being. Many patients lack comprehensive understanding of their health conditions, treatment options and preventive measures. This results in suboptimal management of health conditions, missed opportunities for early intervention and increased healthcare costs.

#### Healthcare Resource Allocation:

By handling routine inquiries and providing triage support, the chatbot can help alleviate the burden on healthcare providers and streamline resource allocation. Users can receive timely advice and guidance from the chatbot, reducing the need for unnecessary clinic visits or phone consultations. Healthcare facilities face challenges in efficiently allocating resources, including healthcare professionals' time and expertise. Non-urgent inquiries and appointments can overwhelm healthcare providers, leading to longer wait times for patients with urgent medical needs.

#### • Continuity of Care:

The chatbot can facilitate continuity of care by serving as a consistent point of contact for users across different stages of their healthcare journey. It can maintain comprehensive records of users' health information, treatment history and preferences, ensuring seamless communication and coordination between healthcare providers. In summary, the development of a medical chatbot aims to address healthcare challenges related to information overload, patient education, resource allocation and continuity of care. By leveraging artificial intelligence and Natural Language Processing

technologies, the chatbot enhances access to healthcare information, promotes patient empowerment, optimizes resource utilization and fosters continuity of care in the healthcare ecosystem.

#### **CHOICE OF TITLE**

Medical chatbots fulfill a number of crucial functions:

#### • 24/7 Availability:

Users can access medical information and guidance at any time of day or night. Users who might have queries or concerns outside of usual clinic hours will find this to be of particular use.

#### • Immediate Responses:

When a user asks a question, chatbots can reply right away, which is useful in an emergency or when someone requires urgent medical assistance.

#### • Health Education:

They can assist consumers learn about various medical issues, treatments and preventive measures by providing accurate and current health information.

#### • Symptom Assessment:

Chatbots can assist users in evaluating their symptoms and offer advice on whether they require additional medical care. This might be especially helpful when people are unclear about the intensity of their symptoms.

#### • Appointment Scheduling:

To improve access to care and streamline the process, certain medical chatbots can help users schedule appointments with healthcare professionals.

#### • Health monitoring and management:

Medical chatbots can also help users monitor their health conditions, remind them to take medication, track symptoms and provide personalized recommendations for healthier living.

#### • Accessibility:

They provide immediate access to medical information and assistance, which is particularly beneficial for people in remote areas or those with limited access to healthcare facilities.

#### • Convenience:

Chatbots offer a convenient way for users to get answers to their medical questions without having to schedule appointments or wait in line. Users can access them from their smartphones or computers anytime, anywhere.

#### • Privacy:

Some people feel more comfortable discussing their health concerns with a chatbot rather than a human healthcare provider due to concerns about privacy and judgment.

#### • Cost-effective Healthcare:

Chatbots can ease the burden on healthcare systems by offering basic medical information and initial triage, which may result in cheaper costs and more efficiency.

#### • Anonymity and Privacy:

Since chatbots allow users to remain anonymous, they might feel more at ease discussing delicate health issues with them.

#### • Advancements in AI and NLP:

Recent advancements in artificial intelligence (AI) and Natural Language Processing (NLP) have significantly improved the accuracy and capabilities of medical chatbots, making them more reliable and effective in understanding and responding to user queries.

In general, medical chatbots supplement traditional healthcare services by providing people with an easy and comfortable way to get healthcare information and support.

#### SYSTEM ANALYSIS

#### **EXISTING SYSTEM**

• A significant number of datasets are needed for Mamta Mittal's FAQ systems.

It merely responds to the same queries.

- In Worker's General Health System is implemented in employee system. It is accessible to a small number of employees.
- In AI-based healthcare chatbot system only medical professionals can respond to inquiries.so there is a significant response time.

- Answers the questions manually on the dashboard system. Humans are fallible beings.so its precision is reduced.
- Umar Jameel does research on chatbots that refer doctors. It is merely a case study. Doctor chatbot deployment is not currently underway.

#### Disadvantages

- The system provides a meaningless response
- There is only basic text
- It is unable to manage loud inquiries.
- It could result in error
- It answers only frequently asked questions

#### BACKGROUND OF THE WORK

Implement Question Answering (QA) systems in the current system. QA systems are information accessing systems that attempt to respond to natural language queries by providing appropriate responses by utilizing natural language techniques and available attributes. The system receives a plain text file as input and its output is a qualified user's answers to all types of questions. A growing number synchronous of people are using written conversations or "chats," as Web-based mental health interventions. Based on an assessment of specific synchronous Web-based chat technologies, this review was created. The available data on the use of this technology indicates a tentative level of support for the intervention mode.

Text-based communication synchronous interventions performed at least as well as the comparison interventions, with better results when compared to waitlist conditions and overall equivalent results when compared to treatment as usual. Future studies will need to consider whether or not these technologies are cost-effective in clinical settings. When compared to standard Web search, medical search has a few special requirements. When someone is uncomfortable but unsure of their specific medical issues, they frequently conduct a medical search. In these situations, the seeker typically wants to learn everything there is to know about the subject at hand. Nonetheless, current medical Web search engines focus their results on a small number of topics and are tuned for accuracy. The nature of medical websites exacerbates this lack of diversity issue. Many medical websites use similar, though not exact, descriptions of medical topics when talking about them by paraphrasing information from research papers and medical textbooks.

#### **PROPOSED METHODOLOGIES**

The user dialogue in the proposed system follows a linear design that starts with symptom extraction, moves on to symptom mapping, which locates the corresponding symptom, diagnoses the patient for a major or minor disease and if the patient is referred to a major doctor, obtains the doctor's information from the database.

The user is identified by the login information that is stored in the database. The logic for state transitions is created, natural language generation templates are employed and the system initiates contact with the user and solicits feedback in order to arrive at an accurate diagnosis. Users can submit their complaints and health-related inquiries with the aid of this system. A primary consideration in the development of this system was customer satisfaction. The chatbot's true purpose is to help people by providing appropriate guidance on leading happy and healthy lives. Because a large number of people lack a basic understanding of their physical condition. Through the chatbot, the user can ask any private question about healthcare without having to visit the hospital in person. by using the Google API to convert text to voice when a medical chatbot is retrieving an answer. The Chatbot receives a query, finds a relevant response and displays it on an Android app. The primary goal of the System in creating this web-based platform is sentiment analysis of customers.

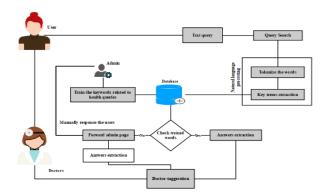

Fig.4 Proposed architecture

A text mining algorithm is used to extract keywords from user-provided queries. then give the results in the form of specific medication information.

#### **INTERFACE CREATION**

All templates are written by using html. Our web page has five sections. The following sections are

#### 1.home

2.doctor login

3.new doctor registration

4.user login

5.new user registration

Once a doctor logs in and sets their password and username. Prior to confirmation, a popup will display the doctor's details and request permission to make sure all of the provided information can be saved.

### Fig.10 New Doctor Registration Code

Fig.9 Doctor's information code

Fig.11 Search information

If a user sign in newly, after setting username and password. Before confirmation the popup will show the patient details to asking permission to confirm all the given details are can be saved or not. admins can use answers to train keywords for processing in the future.

#### **POST QUESTIONS**

Talking with a human can be experienced by the user. In order to diagnose the illness, the bot then poses a series of questions to the user regarding their symptoms. It provides recommendations based on the various symptoms to help identify the illness. Patients can register their information and log in to the system in this module. The questions about health-related matters are then posted. The query may take the form of a textual query.

#### **KEYWORD EXTRACTION**

Natural Language Processing (NLP) is instrumental in keyword extraction, a process of identifying and extracting the most relevant terms or phrases from text data. Here's a succinct summary of its usage in this context:

**1. Text Processing:** NLP techniques preprocess text data by tokenizing it into words or phrases, removing stop words, stemming and lowercasing. This prepares the text for analysis, enhancing the accuracy of keyword extraction.

**2. TF-IDF:** Term Frequency-Inverse Document Frequency (TF-IDF) is employed to assess the significance of words. It assigns weights to words based on their frequency in the document and rarity across a collection. Keywords are identified based on high TF-IDF scores.

**3. Named Entity Recognition (NER):** NER identifies and classifies named entities like persons, organizations and locations. It aids keyword extraction by recognizing entities relevant to the text's context.

**4.Part-of-Speech (POS) Tagging:** POS tagging assigns grammatical labels to words, distinguishing nouns, verbs, etc. This helps prioritize certain word types as potential keywords.

**5.Dependency Parsing:** Dependency parsing analyzes sentence structure to determine word relationships. It identifies semantically related phrases or terms, facilitating keyword extraction.

6. Machine Learning Models: Advanced NLP models, such as recurrent neural networks and transformer models like BERT, are trained on large text datasets to learn word representations. They excel in capturing complex linguistic patterns and contexts, aiding keyword extraction tasks. In essence, NLP techniques enable keyword extraction by processing text data, identifying significant terms based on their frequency, relevance and context.

These methods empower various applications like information retrieval, document categorization and content analysis by extracting valuable insights from textual data. First, questions are gathered and preprocessing procedures are carried out to eliminate distracting words. The basic steps are

• Tokenization

The provided document is divided into one unit or token and is treated as a string for the purpose of identifying each word in the document.

• Elimination of Stop Word

Typical words like a, an, but, and, of, the, etc. are eliminated in this step. A stem is an organic collection of words that have the same meaning or a very close one. Using this method, the root of a word is described. The two types of methods are derivational stemming and inflectional stemming. Porter's algorithm is one of the most widely used stemming algorithms. Next, remove the keywords and move on to the following module.

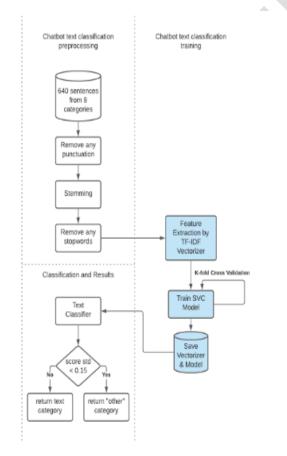

#### Support Vector Algorithm

Support Vector Machines (SVM) are supervised learning algorithms used for classification, regression, novelty and anomaly or outlier detections. algorithm can be trained based on this data such that it can assign future data points into one of the two classes. This algorithm represents the training data samples as points in space such that points belonging to either class can be separated by a wide gap between them, called a hyperplane and the

new data points to be predicted are assigned classes based on which side of this hyperplane they fall into. This process is for a typical linear classification process. SVM can also perform non-linear classification by an interesting approach known as a kernel trick, where kernel functions are used to operate on high-dimensional feature spaces that are non-linear.

Usually, inner products between data points in the feature space help achieve this. With SVM, the optimum result always looks for a greater margin from hyperplane to the support vector and reducing classifying error. But both of that contradicts with each other which is why there's a hyperparameter that needs to be entered to the system for model training. A hyperparameter will impact the result of the machine learning evaluation. A hyperparameter is a constant that is set to change one aspect of the algorithm. In this case the hyperparameter is C, where C controls the margin between the hyperplane and the support vector.

# Fig.12 Data preprocessing for classification prediction

Using Term Frequency - Inverse Document Frequency or TFIDF, words can be converted from string into vector integer that tells how important a word is in a sentence and then stored in binary for it to be used for classification. Before the model can be trained, it needs clean data to produce a good model. The punctuations from 640 sentences with 8 categories or labelled will be removed and then the sentences will be stemmed resulted in only root stems in the sentences. Stop words are removed afterwards leaving behind the most important words in the sentence. The remaining words are vectorized into vector integers using the TF-IDF vectorizer. The data will be stored and trained using SVC algorithm and will be validated using K-fold Cross Validation. K-Fold Cross-Validation is a re-sampling procedure for developing Machine Learning models on limited sample data. This procedure has one parameter (k) which refers to the number of groups to be divided from a data sample. So if the value of k is 5, the number of data samples will be divided into 5 groups. One group will be used as data validation and the rest will be used as training data. After sharing the data, it will be entered into the Machine Learning model and the accuracy value will be calculated.

The accuracy value can be calculated from the total correct predictions, divided by the total predictions. This process will be repeated k times with different data sharing. After the procedure is complete, all accuracy values will be averaged to make the final value .The model is then used to classify user sent messages and responds accordingly

#### TOP K RESULTS

Keywords in this module are forwarded to the server page. Based on the user's symptoms, the chatbot uses a machine learning algorithm to provide tablet details if the user wants a medical diagnosis of the disease.

#### SMS TO VOICE TRANSCRIPTION

The process of text-to-speech involves first analyzing, then processing and understanding the text, after which it is converted to digital audio and spoken. By joining together discrete sound samples,

known as units, this method creates sounds. It generates a user-specific sound sequence from a database created by recording other sequences in speech synthesis. Speech synthesis is used to turn the responses into voice, which microphones then pick up.

#### **RESULTS AND DESCRIPTION**

Having access to healthcare is essential to living a healthy life. However, getting a doctor's consultation when you have health concerns is very difficult. The suggested concept is to use artificial intelligence to develop a medical chatbot that, before speaking with a doctor, can identify a disease and provide basic information about it. The purpose of the medical chatbot is to lower healthcare costs and increase accessibility to medical information. Some chatbots function as medical reference books, educating patients about their conditions and promoting better health. The true value of a chatbot to the user can only be realized when it is able to diagnose any type of illness and provide relevant information. Patients can converse with a text-to-text diagnosis bot about their health concerns and the bot will provide them a personalized diagnosis based on their symptoms. People will therefore be aware of their health and equipped with the appropriate protection.

#### Fig.16 Drug details

Performance metrics can be used to assess word classification. The accuracy parameter can be used to determine the system's performance.

#### ACCURACY

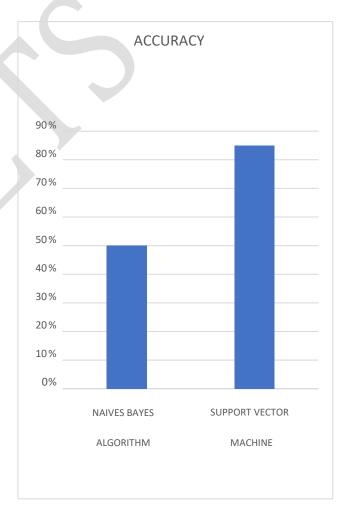

Accuracy (ACC) is found as the fraction of total number of perfect predictions to the total number of

test data. It can also be represented as 1 - ERR. The finest possible accuracy is 1.0, whereas the very worst is 0.0.

$$ACC = \frac{TP + TN}{T}$$
 x 100  $TP + TN + FN + FP$ 

- True positive (TP): number of true positives perfect positive prediction
- False positive (FP): number of false positives imperfect positive prediction
- True negative (TN): number of true negatives perfect negative prediction False negative (FN): number of true negatives imperfect negative prediction

The experimental results of multiple images shown in following table and Figures.

#### Fig.17 Comparison chart

In comparison to current machine learning algorithms, the suggested system offers better accuracy and faster classification task execution.

#### International Journal On Engineering Technology and Sciences – IJETS ISSN (P):2349-3968, ISSN (O): 2349-3976 Volume XI - Issue V, May – 2024

We have developed a system in this system that can assist medical facilities or hospitals in allowing their patients to freely ask voice inquiries about medical dosages. The system speaks out and displays all medicine names after receiving the medicine API output. The reason we use Natural Language Processing (NLP) is to enable computer-user communication on their terms. The health care transactions generate a large amount of data that is too complex and diverse to be evaluated by conventional methods. Data mining can be used to uncover new, practical and possibly life-saving information from medical data. Data mining is the process of extracting or mining knowledge from vast amounts of data. It is regarded as an innovation that tends to benefit doctors who work with a lot of data. Based on symptoms, a medical chatbot offers individualized diagnoses.

#### **FUTURE ENHANCEMENT**

Future hospital management software will be datadriven, using advanced analytics to generate insights and support strategic planning. Real-time tracking, predictive modeling, trend analysis and automated reporting will enable healthcare administrators to monitor performance, uncover areas of inefficiency and make timely interventions. This places evidence-based decision-making at the fingertips of healthcare providers. Hospital management software of the future will feature integrated telemedicine platforms, allowing hospitals to provide virtual consultations, manage remote patient monitoring and maintain electronic health records seamlessly. 3. Future software will focus on providing personalized patient portals, facilitating easy access to their health records, medication reminders and teleconsultations. The ability to design and manage workflows will be an essential feature of future hospital management software.
